# Problems with Cloud security

Objectives:

- Enforce security properties
  - Confidentiality, Integrity, Availability
- Check security properties enforcement
  - Assurance, Assurance Scripts
- Many available system and network security mechanisms
  - iptables
  - SELinux
  - Secure Elements (SE)
  - OpenVPN
  - ...
- Complexity of security configuration
  - System, VM, Host, Hypervisor, Network, ...

No security mechanism can protect a whole system/Cloud on its own  $\Rightarrow$  Propose a model to easily guarantee security properties.

## **Global Objective**

Automatic deployment of security and assurance in a Cloud environment

- Define the global Cloud software architecture
- Define the security requirements using properties
- Enforce the security properties using existing mechanisms
- Check that the security properties are enforced as expected

# **Global Architecture**

Seed4C's solution: a three-parts model

- A modeling tool (GUI)
  - The user describes his software architecture
  - He graphically defines abstract security properties (Confidentiality, ...)

#### A distribution engine

CLHS'15

Splits the properties into sub-properties to be applied on the nodes
 An enforcement & assurance engine: the SE<sup>E</sup> (Secure Element Extended)

• Selects and configures the Software Security Mechanisms (SSM)

# **Global Architecture**

# Security Policy Language

To easily express the security requirements, we propose a dedicated language with:

#### • Contexts:

• Identify the resources (VM, applications, processes, users, files...)

### • Properties:

• Define the security requirements between contexts

### Security Contexts

- A context is a label identifying a real resource
- It is composed of a set of attributes
- Each attribute characterizes a part of the identified resource
  - IP address, localization, encryption key, owner identity...
- Reports owned by Bob:

Type.Passive.Data.File="report":Id.Username="bob"

# Security properties

Property Templates:

• Two blocks: enforcement & assurance

### • Defined using capabilies

- Capability = abstract functionality offered by security mechanisms
- Enforcement
  - generate key: generate an encryption key
  - deny all write accesses: deny all write accesses to a resource
- Assurance
  - check encrypt flow: check that a network flow is encrypted
  - check write: check that resource cannot be read

Property instances:

- Defined during modelization
- Only Bob can read his report files:

Confidentiality (Type.Passive.Data.File="report":Id.Username ="bob", Id.Username="bob")

11 / 25

< □ > < □ > < □ > < □ > < □ > < □ >

## Security properties

Property Templates:

- Two blocks: enforcement & assurance
- Defined using capabilies
  - Capability = abstract functionality offered by security mechanisms
  - Enforcement
    - generate key: generate an encryption key
    - deny\_all\_write\_accesses: deny all write accesses to a resource

Assurance

- check encrypt flow: check that a network flow is encrypted
- check write: check that resource cannot be read

Property instances:

- Defined during modelization
- Only Bob can read his report files:

Confidentiality (Type.Passive.Data.File="report":Id.Username ="bob", Id.Username="bob")

11 / 25

A B M A B M

# Security properties

Property Templates:

- Two blocks: enforcement & assurance
- Defined using capabilies
  - Capability = abstract functionality offered by security mechanisms
  - Enforcement
    - generate key: generate an encryption key
    - deny\_all\_write\_accesses: deny all write accesses to a resource

Assurance

- check encrypt flow: check that a network flow is encrypted
- check write: check that resource cannot be read

Property instances:

- Defined during modelization
- Only Bob can read his report files:

Confidentiality (Type.Passive.Data.File="report":Id.Username

```
="bob", Id.Username="bob")
```

### Property Templates: Example

• File confidentiality through access control:

```
boolean Confidentiality Access Control (Type.Passive.Data.File SCFile, Id.User SCUser) {
 enforcement {
   deny all read accesses (SCFile);
    return allow read access (SCFile, SCUser);
  }
 assurance {
   boolean c = true:
    for (SCUserTmp IN get all users()) {
      if (SCUserTmp.Id.User == SCUser.Id.User) {
       c &= check read (SCFile, SCUser);
     } else {
        c &= (NOT check read (SCFile, SCUser));
      }
    }
    return c;
```

CLHS'15

- 2 Architecture
- 3 Language

#### 5 Experiment

#### Conclusion

## Assurance property

#### Assurance generation

- Two types:
  - Assurance for mechanisms: generated by each plugin
  - Assurance for properties: defined with the properties, using the language
- Generate scripts
- Scripts' execution defined in an Assurance property:

```
T3:= boolean Assurance (Tests.Frequency SCFrequency) {
    enforcement {
        return run_xccdf_tests (SCFrequency);
     }
}
```

### Assurance engine

Enforcement and assurance projection for mechanisms:

 $\mathsf{Policy} \to \mathsf{Contexts}, \, \mathsf{Properties} \to \mathsf{Plugins} \to \mathsf{Mechanisms} \; \mathsf{Configuration}$ 

CLHS'15

15 / 25

・ロト ・ 一下 ・ ・ 三 ト ・ 三 ト

## Assurance

What is generated:

- Scripts to check mechanisms' status
- Scripts to check properties' enforcement

What is done:

- Scripts are executed by a plugin (e.g. Oscap) according to Assurance properties
- Results stored in XCCDF file

- 2 Architecture

- XCCDF file generate by the  $SE^E$  and used by Oscap
- Test the enforcement of the properties
- Can also be used to test the status of the mechanisms

```
$ cat prop-xccdf.xml
[...]
<Rule id="prop-fileConf" severity="medium" selected="true">
<title>Confidentiality Status</title>
<description>Check that property is properly enforced</description>
<check system="http://open-scap.org/page/SCE">
<check system="http://open-scap.org/page/SCE">
<check - import import - name="stdout" />
<check-content-ref href="fileConf.sh"/>
</check>
</Rule>
[...]
```

A B K A B K

#### • Assurance script generated by the SE<sup>E</sup>

```
$ cat_fileConf_sh
#!/bin/bash
RET=$XCCDF RESULT PASS
check read(){su -c "test -r "$1"" $2; return $?;}
FILES=[...] # list of confidential files
USERS=[...] # list of all users
OK USERS=[...] # list of authorized users
for file in "${FILES[@]}"; do
 for user in "${USERS[@]}"; do
 check read $file $user
 READ OK=$?
  if [[ " ${OK USERS[@]} " =~ " $user " ]]; then
   if [[ $READ OK -ne "0" ]] : then
   RET=$XCCDF RESULT FAIL
   echo "Unexpected access denial: $user->$file"
   fi
  else
   if
      [[ $READ OK -eq "0" ]]; then
   RET=$XCCDF RESULT FAIL
   echo "Unauthorized access: $user->$file"
   fi
  fi
done
done
exit $RET
```

#### Assurance stats

| Number of  |   |
|--|---|
| Security properties                                    | 8 |
| Assurance aggregation properties                       | 1 |
| SSMs collaborating to enforce the security properties  | 4 |
| (SELinux, iptables, PAM, SSH)                          |   |
| SSMs collaborating to enforce the assurance properties | 1 |
| (Oscap)  |   |
| Assurance scripts for the properties                   | 8 |
| Assurance scripts for the SSMs                         | 4 |

# Conclusion and future works

Conclusion:

- A new language to express security properties in a distributed and heterogeneous environment
- An architecture to enforce the security policy and to check the enforcement
- A solution independent from the security mechanisms
- Experiments on industrial usecases defined by partners of the European project Seed4C (http://www.celticplus-seed4c.org/)
- Now: automatic reconfiguration of mechanisms when the assurance process detects an error

Future works:

• Check the coherence of the properties before enforcement
